IAP5 Rec'd PCT/PTO 30 MAR 2006

Method and System for Configuring the Language of a Computer Program

The invention relates to a method in accordance with the precharacterizing part of patent claim 1 and to a system in accordance with the precharacterizing part of patent claim 7.

If a computer program is to be used in various countries or regions with a respective different language then it is frequently desirable to match the graphical display of the computer program and particularly the dialogs of the user interface for the program to the respective language of the country or region. In this case, the display of a starting language e.g. set as standard - for example German - is changed to a preferred selection language - for example English.

This operation of matching the language of a computer program to various other languages, usually called "localization" on the basis of the prior art, is assisted, on the basis of the prior art, by virtue of the computer program already being designed for simple localizability at the design stage. This form of program design is called "Internationalization" on the basis of the prior art.

Existing approaches to internationalization firstly provide for wildcard expressions to be provided in the source text of the computer program instead of the texts which are to be used for the dialogs in the computer program, such as menus, buttons or texts for direct help. These wildcard expressions are then used in all parts of the computer program instead of the relevant message texts, that is to say those parts which are displayed to the user of the computer program. In particular parts of the source text of the computer program, for example in "header files", compiler definitions are then created, for example "# define" expressions, in which the

1 wildcards are attributed the desired message texts in a
2 particular national language. While the computer program
3 source text is being compiled, the compiler then first of
4 all replaces every wildcard which occurs in the source text
5 with the message text in line with the compiler definition
6 from the relevant part of the computer source text.

7
8 The effect achieved by this is that localizing to a
9 particular national language requires only the relevant
10 compiler definitions to be replaced, which are then replaced
11 in the source text by the compiler during the compiling
12 process.

13
14 However, this method has the practical drawback that
15 localizing the computer program requires said method to be
16 in the computer program's source text. This is a drawback
17 particularly when localization matching operations are to be
18 performed in the branch in the respective target country,
19 for example, or specific matching operations are to be
20 performed for a customer in situ, for example. In these
21 cases, it is frequently not desirable to pass on the entire
22 source text of the program. In addition, this method
23 requires an appropriate development environment for
24 compiling the program, which gives rise to additional
25 complexity of engineering, time and cost.

26
27 On the other hand, it is known practice on the basis of the
28 prior art to precompile a program in modular fashion such
29 that all language-specific parts of a program are arranged
30 in separate parts of the binary computer program, known as
31 dynamic link libraries (DLLs). In this case, entry addresses
32 are provided between the individual DLLs, so that the
33 relevant parts of the binary - that is to say already
34 compiled and executable - computer program are assembled in
35 a well defined manner. It is thus possible for a first part
36 of the binary computer program to call the country-specific
37 message text at a particular entry address for a
38 country-specific DLL.

1
2 Although this method no longer requires the entire source
3 text to be present for localizing the computer program, it
4 is nevertheless necessary to disclose the country-specific
5 parts of the source text which are intended to have the
6 language matching performed for them, and in this case too
7 the localization requires the presence of an appropriate
8 development environment together with a compiler in order to
9 create a DLL from the localized source text parts.

10
11 This is an obstacle particularly for when small changes are
12 made retrospectively for a customer or by the customer
13 himself.

14
15 It is an object of the present invention to specify a method
16 and a system for configuring the language of a computer
17 program which avoid the drawbacks discussed above and allow
18 retrospective matching of the language of an executable
19 computer program in binary form, particularly with little
20 complexity.

21
22 This object is achieved by a method in accordance with
23 patent claim 1 and by a computer system in accordance with
24 patent claim 7.

25
26 The effect achieved by finding identification expressions in
27 a text memory which are associated with wildcard character
28 strings contained in the computer program and replacing the
29 wildcard character strings in the computer program with the
30 associated message character strings in the text memory
31 during the runtime of the executable binary computer program
32 is that language configuration or localization, i.e.
33 matching the wording of the message character strings,
34 requires no manual or automated action to be taken in the
35 source text of the computer program. This allows
36 localization or retrospective matching to be performed
37 without recompiling and hence without the development
38 environment which is required for recompiling.

1
2 This also allows language matching to be performed during
3 continuous use of the computer program too, i.e. without
4 stopping or terminating the running computer program.
5

6 The fact that said replacement of the wildcard character
7 strings in the computer program with associated message
8 character strings in the text memory is effected by
9 attributing the message character strings to memory
10 variables in the running computer program means that it
11 becomes possible to leave the binary computer program
12 unchanged during localization matching, while only dynamic
13 contents of the store associated with the computer program
14 change during said replacement operations. Particularly in
15 contrast to the storage of static character string
16 constants, this is done at stipulated entry addresses, as
17 are used when using dynamic link libraries (DLLs).
18

19 The effect achieved by the interaction of these features is
20 that the computer program does not need to have its
21 executable binary code changed in order to perform language
22 matching.
23

24 These advantages are achieved in appropriate fashion in the
25 inventive computer system by virtue of the computer program
26 being in executable binary code, and means for finding
27 identification expressions in a text memory which are
28 associated with wildcard character strings contained in the
29 computer program and for replacing the wildcard character
30 strings in the computer program with the associated message
31 character strings in the text memory being contained in the
32 computer program.
33

34 Another advantageous effect which this achieves is that it
35 avoids a specific software tool for creating and compiling
36 the points in the source text of the computer program which
37 relate to the language display being introduced into the
38 system in addition to the computer program and hence giving

1 rise to an increase in complexity. This also significantly
2 simplifies the incorporation of the program code used for
3 finding items in the text memory and replacing items in the
4 computer program's store into the computer program which is
5 to be localized.

6
7 Advantageous developments of the invention are possible in
8 the subclaims referring back to claim 1 and to claim 7 and
9 are explained briefly below:

10
11 If the method is advantageously developed such that the text
12 memory is selected so that the identification expressions
13 contain alphanumeric name descriptors and alphanumeric field
14 descriptors and that a respective field descriptor has an
15 associated message character string, then it becomes
16 possible to combine a plurality of pairs of values, each
17 comprising an alphanumeric field descriptor and a message
18 character string, to produce a superordinate data structure
19 which is identified by means of the name descriptor and to
20 address them as a group using said alphanumeric name
21 descriptors. In this way, all the message character strings
22 associated with a dialog, for example for buttons in a
23 dialog and for pop-up context message texts, can be
24 addressed as a group using the common name descriptor in a
25 single, common reference by a suitable wildcard character
26 string in the computer program.

27
28 If the method is advantageously developed such that an
29 identification expression in the text memory is found for a
30 wildcard character string contained in the computer program
31 by evaluating a path for the wildcard character string,
32 which path is formed from at least one of said name
33 descriptors, then it becomes possible to address a specific
34 name descriptor in a logically consistent manner when a
35 plurality of name descriptors are nested in one another.
36 Such hierarchically nested name descriptors make it
37 possible, by way of example, to set up local validity areas
38 for name descriptors, which improves the extendability of

1 the system and reduces the susceptibility to errors during
2 localization.

3
4 In this case, in line with the order of the name descriptors
5 of the path, the nested name descriptors in the text memory
6 are addressed until there are no further name descriptors
7 along the path and the pairs of values can be clearly
8 determined and read from the field descriptor and the
9 message character string.

10
11 The use of a path comprising alphanumeric name descriptors
12 as a wildcard character string in the computer program is
13 particularly advantageous because such a character string,
14 according to the type of data structure, is similar to the
15 replacing message character string and can therefore be
16 easily processed during the replacement operation.

17
18 If the method is developed such that the XML format is
19 selected for the design of the text memory, and the
20 identification expressions are found by interpreting XML
21 tags, then a popular, cross-platform data format is chosen
22 which can be handled by a large number of editors and which
23 has a syntax which can easily be checked for errors and
24 inconsistencies to a large extent using popular methods.

25
26 The XML language definition referred to here and in the
27 whole of the present description, and conceptualities in
28 this regard, are disclosed in Bray et. al.: "Extensible
29 Markup Language (XML) 1.0 (Second Edition), W3C
30 Recommendation, October 6, 2000. The XML tags are used to
31 find a form for the alphanumeric identification expressions
32 which is suitable for the XML format.

33
34 If the XML text memory, for example an XML file, is selected
35 such that it is structured in the form of an XML table then
36 an XML-suitable form is specified in which the nested name
37 descriptors which have been selected for storage are the
38 relevant XML tags forming an XML table.

1
2 If the method is advantageously developed such that the
3 wildcard expressions to be replaced are respectively read
4 from a memory variable in a dialog structure in the computer
5 program, then it is a particularly simple matter to use
6 software which exists during program design and
7 implementation to create dialogs for the user interface of a
8 computer program without needing to make any changes to this
9 existing software. In this way, the dialog can be created,
10 for example using a graphical dialog editor, in a
11 conventional fashion and the wildcard character string can
12 be input instead of the dialog text which normally needs to
13 be input.

14
15 The computer system can advantageously be produced in line
16 with the above developments of the method.

17
18 The features of all the claims can advantageously be
19 combined in any manner within the context of the invention.

20
21 In line with the advantageous embodiment of the text memory
22 in XML format, the name descriptors used in the
23 advantageously developed computer system for language
24 configuration, too, may be shown as XML tag names and field
25 descriptors may be shown as XML attribute names.
26 Accordingly, the message character strings in the text
27 memory of this type are shown as XML attribute values. The
28 terms XML tag name, XML attribute name and XML attribute
29 value are accordingly defined as tag name, attribute name
30 and attribute value in said W3C recommendation dated October
31 6, 2000.

32
33 The method and the system can be developed such that the
34 wildcard character string, which may advantageously be
35 stored in a memory variable in a dialog structure in the
36 computer program, starts with a characteristic prefix,
37 preferably comprising alphanumeric symbols. As a result,
38 such character strings stored in a dialog structure, which

are wildcard character strings, can easily be distinguished from character strings which are not to be localized in dialogs in the user interface of the computer program.

The invention is explained below with reference to an exemplary embodiment, a source text listing and a few figures, in which:

figure 1 shows the schematic illustration of a dialog box with three dialog elements, each containing a wildcard character string as dialog text,

figure 2 shows a code fragment as an example of the use of the method implemented in a language handler object,

figure 3 shows a text memory, in the form of an XML file, with entries in the form of an XML table,

figure 4 shows the dialog shown in figure 1 after the replacement method has been carried out for this dialog, and

figure 5 shows a schematic illustration of a computer system for carrying out language matching for the display of a computer program.

Figure 1 shows a dialog box in a user interface of a computer program with a text field 1, a first button 2 and a second button 3. This dialog box may have been created, by way of example, using ordinary program libraries for creating graphical user interfaces (GUI libraries), for example by programming or by using a development tool for a computer-aided development of user interfaces. The text usually contained in the popular graphical elements, in this

1 figure the text which is contained in the text field 1, in
2 the first button 2 and in the second button 3, has usually
3 been attributed as a character string parameter (for example
4 "string"), as in the aforementioned development methods for
5 user interfaces.

6
7 In this example, these character strings are in the form of
8 wildcard character strings which start with a characteristic
9 prefix, for example two successive paragraph characters. In
10 this way, wildcard character strings can easily be
11 distinguished from dialog texts, which are not wildcard
12 character strings, in the subsequent method.

13
14 For the rest, the wildcard character strings are constructed
15 from name descriptors in the form of XML tag names, in the
16 present case "SICAMPAS", "ConfigurationTool" and
17 "HelloWorld", for example, in text field one, and
18 "SICAMPAS", "Common" and "OK", for example, in the first
19 button 2. These are separated from one another by oblique
20 strokes. This produces a path comprising XML tags or name
21 descriptors, which allow the nested name descriptors to be
22 resolved in the subsequent method, or allow the desired
23 entry to be found in an XML table.

24
25 Accordingly, the text character strings for the buttons 2
26 and 3 are constructed from a characteristic prefix, XML tags
27 as name descriptors and separating oblique strokes to
28 produce wildcard character strings which, minus the
29 characteristic prefix, produce an XML path.

30
31 Figure 2 shows a C-Sharp code fragment which might be
32 associated with a dialog box in figure 1 by way of example.
33 This produces an instance of a language handler object and
34 transfers to it the name of an XML file "english.xml" as a
35 parameter. This XML file is a text memory within the context
36 of the invention, the design of which is described by way of
37 example below in figure 3.

38

1 Following initialization of the dialog element shown by way
2 of example in figure 1 by the instructions
3 "InitializeComponent", an object from the class
4 LanguageHandler is produced, as explained above, which for
5 its part uses the aforementioned XML file as a text memory.

6
7 To prompt the actual localization process, that is to say
8 the replacement of the wildcard character strings shown in
9 the dialog elements 1, 2 and 3 in figure 1 with the desired
10 message character strings, the method "InitializeControl"
11 from the aforementioned language handler object is called in
12 the present code fragment in figure 2. However, this
13 function call can also be made by any other programming
14 methods which are usual in the field.

15
16 Having been initiated by this function call, each dialog
17 element 1, 2 and 3 in figure 1 is now successively visited
18 during the further program/method execution, a check is
19 performed to determine whether the character string which is
20 present in the respective dialog element is a wildcard
21 character string by looking for the characteristic prefix
22 ("\$\$"), and then the characteristic prefix is removed from
23 the respective wildcard character string and the remaining
24 XML path is used to read the entry addressed by this path in
25 the XML file, which has already been opened during
26 production of the language handler object. After that, the
27 value associated with the entry, namely the message
28 character string, is substituted for the character string
29 originally contained in the respective dialog element, i.e.
30 the wildcard character string stored in the respective
31 dialog element is replaced with the relevant message
32 character string which has been ascertained. Within this
33 context, it is possible for a single path stored as a
34 wildcard character string in the respective dialog element
35 to replace a plurality of associated character string
36 values, too, for example ToolTip texts (explanatory texts
37 which pop up on the basis of the position of a mouse pointer

1 on the display panel) associated with the dialog elements 1,
2 2 and 3, or status bar texts.

3
4 Figure 3 shows an exemplary embodiment of the design of the
5 text memory in XML format. Name descriptors contained in an
6 identification expression are in this case in the form of
7 XML tags which are each enclosed by angled brackets. Field
8 descriptors contained in identification expressions in the
9 text memory are in this case in the form of XML attribute
10 names, which are situated on the left-hand side of an equals
11 sign. On the right-hand side of the equals sign, enclosed by
12 quotation marks, the replacing message character strings are
13 stored, as XML attribute values. In this context, attribute
14 names and attribute values form pairs of values in the XML
15 text memory.

16
17 The first button 2 in figure 1 is used to describe the
18 ascertainment of the message character strings associated
19 with wildcard character strings contained in the computer
20 program. As already outlined, the character string
21 originally stored in the dialog element is adjusted for the
22 characteristic prefix, and the remaining part is interpreted
23 as a path comprising XML tags in order to localize the
24 relevant entry in the text memory. In this case, said path
25 represents the key criterion which is used to interpret the
26 characters contained in the XML text memory, so that the
27 entry being sought can be localized. These characters
28 contained in the text memory in the syntax or in the format
29 of the text memory form the respective identification
30 expression associated with the path, which expression
31 contains not only special characters but also tag names and
32 attribute names. The path "SICAMPAS/Common/OK", considered
33 to be an XML path, thus results in the identification
34 expression being found, which is constructed from the nested
35 XML tags <SICAMPAS>, <Common> and <OK Text= ToolTip=/>.

36
37 When this entry has been distinctly localized in this way,
38 the message character string ("OK") associated with the XML

1 attribute name is substituted for the wildcard character
2 string. This replacement is made by attributing it to the
3 memory variable under which the wildcard character string
4 was previously stored. Accordingly, the wildcard attribute
5 value associated with the attribute name "ToolTip" is
6 attributed to the relevant memory variable for the dialog
7 structure. To this end, this memory variable does not need
8 to have been filled with a particular value beforehand.
9 Figure 4 shows, by way of example, the result of the
10 completed replacement method for the dialog elements shown
11 in figure 1 using wildcard character strings. The wildcard
12 character strings contained in the dialog elements 1, 2 and
13 3 in figure 1 have been replaced in the manner described
14 above, using the text memory shown in figure 3, with the
15 associated message character strings in said text memory,
16 and now form the textual content of the dialog elements 1, 2
17 and 3 in figure 4. ToolTip texts are not shown in more
18 detail in this figure.

19
20 In this way, a simple change to the content of an XML file
21 which is shown in figure 3 can be matched to the textual
22 contents of dialog elements in the user interface of a
23 computer program, for example as part of localization to the
24 target language of a country or of a region, without any
25 change needing to be made to the binary code of the
26 executable computer program. In addition, the use of XML
27 paths specifies a method for addressing entries in the text
28 memory which is easy for people to understand and which
29 allows people to find entries easily, particularly when
30 nested name descriptors are being used, without this
31 requiring the entire document to be searched line by line.

32
33 The fact that no further association tables, such as tables
34 with associations between numerical IDs and associated
35 character strings, or wildcards are required reduces the
36 complexity of maintenance and achieves better clarity. In
37 addition, only a single resource exists for a dialog in the
38 user interface, which means that synchronization of the

1 resources in various languages among one another is
2 dispensed with.

3
4 Finally, figure 5 shows a computer system 11 in a type of
5 block diagram by way of example. The computer system 11 in
6 this context may be any electrical appliance whose functions
7 are performed at least partly under the control of a
8 microprocessor 12, for example a personal computer, mobile
9 telephones, consumer electronics appliances or else
10 automation appliances in automated processes, e.g.
11 protective devices and controllers in power supply and
12 distribution systems. Such an appliance normally has a
13 display apparatus 13, e.g. a monitor or a display. The
14 display apparatus 13 has a display panel 13a, for example
15 the screen surface of a monitor, and a display control 13b,
16 e.g. with control programs such as drivers for producing a
17 display on the display panel 13a and display memories for
18 buffer-storing elements of the display. By way of example,
19 the display panel shows display objects 14a and 14b, which
20 have texts (not shown in figure 5) in a starting language
21 which is displayed first of all.

22
23 To change the language displayed from the starting language
24 to a preferred selection language, a command from a computer
25 program executed by the microprocessor 12 is used during
26 operation of the computer system to examine memory areas in
27 the computer system which are associated with the display
28 objects 14a and 14b - e.g. the display memories of the
29 display control 13b - for wild card characteristics, e.g.
30 paths comprising XML tags, under microprocessor control.
31 These are replaced in identification expressions and
32 transferred to a text memory chip 15 in line with the
33 procedure explained further above under the control of the
34 microprocessor 12. This text memory chip 15 contains, in a
35 text memory, e.g. an XML table, message character strings in
36 the selection language which are associated with these
37 identification expressions. Upon request by the
38 microprocessor 12, message character strings associated with

1 corresponding identification expressions are ascertained and
2 are transferred to the microprocessor 12 and then to the
3 display memory of the display control 13b. Finally, the
4 message character strings in the (newly selected) selection
5 language are inserted into the display objects at the
6 positions prescribed by the wildcard character strings
7 instead of the previous character strings in the starting
8 language. The display objects 14a and 14b are then displayed
9 in the preferred selection language.

10
11 In summary, the computer system 11 shown in figure 5 is
12 thus, in the general sense, an electrical appliance with at
13 least one microprocessor 12 and a display apparatus 13 on
14 which at least one display object 14a, 14b is shown in a
15 starting language. A selectable text memory chip 15 is
16 provided which contains alphanumeric message character
17 strings in the selection language which are associated with
18 alphanumeric identification expressions. To change from the
19 starting language to the selection language which is to be
20 displayed from now on, this chip outputs message character
21 strings in the selection language which are associated with
22 selected identification expressions, upon request by the
23 microprocessor 12, when an identification expression is
24 applied to it which corresponds to a wildcard character
25 string associated with the at least one display object 14a,
26 14b.

27
28 In practical operation, it is possible to reconfigure a
29 program or a computer system to a language other than the
30 one currently being used by simply replacing a file
31 contained in the text memory, for example by simply copying
32 over this file. Using the code fragment shown in fig. 2,
33 this could be achieved by replacing the file english.xml
34 with an altered or completely different file called
35 english.xml, for example. This allows spelling mistakes and
36 grammatical errors, for example, in the original xml file to
37 be corrected in situ on the customer's premises too, since
38 it is not necessary to regenerate software. The listing

below gives a detailed description of an implementation based on the method in a computer system in the language C-Sharp:

```
using System;
using System.Xml;
using System.Xml.XPath;
using System.Windows.Forms;
using System.IO;

namespace Siemens.PTD.Sicam.PAS.LanguageHandler
{
    /// <summary>
    /// This class contains all required operations for
    /// the language handling
    /// </summary>
    public class LanguageHandler
    {
        #region Protected Members

            protected XmlDocument m_Doc;
        #end region

        #region Construction / Dispose

            /// <summary>
            /// Constructs a ResourceManager object.
            /// </summary>
            /// <param name="languageFilePath">Path to language
            table</param>
            public LanguageHandler (string languageFilePath)
            {
                m_Doc = new XmlDocument();
                m_Doc.Load(languageFilePath);
            }

        #endregion

        #region Public Methods

            /// <summary>
            /// Initializes the language of a Control and its
            context menu.
            /// </summary>
            /// <param name="ctrl">Control to be initialized</param>
            public void InitializeControl(Control ctrl)
            {
                if (ctrl == null)
```

```
1             return;
2
3             HandleControlLanguage(ctrl);
4             InitializeControl(ctrl.ContextMenu)
5         }
6
7         /// <summary>
8         /// Initializes the language of a Menu and all its
9         items.
10        /// </summary>
11        /// <param name="ctrl">Menu to be initialized</param>
12        public void InitializeControl(Menu mnu)
